Detection of possible new cytogenetic alteration by arrayCGH related to dysmorphia in the hands

M. Del Aguila García1, M. Molina Zayas1, S. García Chileme1, M. Pérez Sanchez2, A. Mora Guijosa1, T. De Haro Muñoz2, 1Hospital Universitario Virgen de las Nieves, Granada, Spain, 2Hospital Campus de la Salud, Granada, Spain

Background: Comparative Genomic Hybridization Arrays (CGHarrays) are technologies that allow detecting losses or gains of genetic material and unbalanced rearrangements throughout the genome with high sensitivity, speed and resolution.

Methods: A 13 year old patient with a possible dysmorphic syndrome is studied for presenting disorder of the joint movement of the fingers of both hands that hinder movement. As a family history he emphasizes that his father has similar alterations in the fingers. The arrayCGH is carried out with the Perkin-Elmer platform which has an average resolution of 20kb and of 10kb in the regions of interest. The Genoglyphix software is used to interpret the results.

Results: A deletion of 1.98 Megabases is detected in the chromosomal region 1q41. The study is also carried out in his father for presenting also the pathology detecting the same alteration found in his son.

Conclusion: The deletion found has not been associated to date pathology or poly-morphism, so it could be considered as of clinical significance uncertain, but when detected also in the parent with a high probability could be cataloged this alteration as the Cause of pathology. With this technique can be revealed alterations that can be cause of mental retardation, intellectual disability, dysmorfias and/or malformations, which represent a major public health problem. Thanks to the arrayCGH, the proportion of cases whose etiology is unknown can be minimised.

A case of 4p deletion syndrome inherited from an affected parent without phenotypic features

F. K. Marques1, S. D. L. Cueva2, E. Cueva Mateo2, C. S. F. Ferreira1, 1Hermes Pardini Institute (Research & Development Division), Vespasiano, Brazil, 2Hermes Pardini Institute (Cytogenetic Division), Vespasiano, Brazil

Background: Partial deletions of the short arm of chromosome 4 is associated with a clinically recognizable syndrome. Wolf-Hirschhorn syndrome (WHS) is a rare chromosomal disorder caused by terminal deletion of the short arm of chromosome 4. About 50%-60% of individuals with WHS have a de novo deletion and about 40%-45% have an unbalanced translocation with a deletion of 4p. These unbalanced translocations may be de novo or inherited from a parent with a balanced rearrangement. The clinical picture includes facial anomalies, growth retardation, mental retardation, seizures and defects in the brain, heart and palate. It is reported that the sizes of 4p deletions are variable and the clinical findings are different from classic WHS according to the deleted portion. The critical region for WHS is located on the terminal part of the chromosome 4p, with a length of approximately 1-5 Mb. The severity of the clinical presentation is variable depending on the haploinsufficiency of genes in a deleted region.

Objective: To report a case of a maternally inherited 4p deletion from asymptomatic woman analyzed by G-banding karyotype by array-based comparative genomic hybridization (array-CGH).

Case report: We report four-year-old boy with severe hypotonia, hypospadias, psychomotor development delay, hypertelorism, cardiac anomalies, seizures and defects in the brain. He was born to nonconsanguineous and asymptomatic parents, with no history of abortions. G-band chromosome analysis revealed the karyotype 46, XY, del(4)(q16). His father had a normal karyotype (46,XY), but the maternal chromosomal analysis revealed the 46,XX,add(4)(p15.2) karyotype. The proband’s array-CGH analysis revealed an 8.6 Mb pathogenic deletion in the chromosome 4p16.3p16.1 [chr[4p16.3:180,743,8-7,802,370)x1], encompassing more than 80 genes, including the WHS critical region. Maternal CGH array analysis revealed an interstitial 5.5 Mb deletion in the chromosome 4p16.3p16.1.

This deletion includes several OMIM genes such as HTT, DOK7, ADRA2C, EVC, EVC2, but these genes alone were not related to any phenotype, except for the MSX1 and WFS1 genes. The WFS1 gene is located in the retinohypothalamic pathway, and the haploinsufficiency of the MSX1 gene is associated with selective dental agenesis. Thus, a smaller deletion was detected in this case, excluding the WHS critical region. The recurrence of WHS in the child was not due to a parental balanced translocation, but it was due to a different mechanism, the meiotic amplification of a smaller deletion present in the mother, most likely. This case highlights the importance of an integrated approach to cytogenetic analysis and array-CGH analysis.

Expression of Tim-3 in PBMCs and Placental Tissue in Unexplained Recurrent Spontaneous Abortion

X. Zhuang, Qilu Hospital of Shandong University, Jinan, China

Background: The expression of the T-cell immunoglobulin domain, mucin domain-3 (Tim-3) in unexplained recurrent spontaneous abortion (URSA) was investigated.

Methods: im-3 mRNA expression in peripheral blood mononuclear cells (PBMCs) of URSA and control groups was assayed by fluorescent quantitative real-time polymerase chain reaction. Tim-3 protein expression intensity and localization in placental villi and uterine decidua were determined using immunohistochemical assay.

Results: Tim-3 mRNA expression in PBMCs was significantly higher in URSA than in normal controls (1.32 ± 0.13 vs. 1.20 ± 0.06, P < 0.01). Tim-3 was expressed in placental tissue from both URSA patients and normal pregnant females (controls), however, the expression intensity was higher in the URSA group (P < 0.05).

Conclusion: Increased Tim-3 expression in PBMCs may affect maternal-fetal immune tolerance and facilitate pathogenesis of URSA.

distribution of the genotype of interleukin-28b sr12979860 in patients with chronic hepatitis c studied in our hospital area

M. Viloria Peñal1, E. Lepe Balsalobre1, J. Peral Camacho1, J. Guerrero Montavez2, A. Moro Ortiz3, 1Virgen de Valme University Hospital, Seville, Spain, 2Virgen del Rocio University Hospital, Seville, Spain

Background: According to data from the World Health Organization, infection with the hepatitis C virus represents a serious global health problem, since it is estimated that it affects approximately 180 million people, of which 70-80% will develop an infection chronic. In these patients with chronic infection, the polymorphism rs12979860 of IL28B has been described as an important predictor of response to treatment with pegylated interferon alfa (INF alpha) and ribavirin. Thus, patients carrying the CC polymorphism have percentages higher than 80% sustained viral response (SVR), while CT and TT patients have SVR rates of less than 50%. The aim of this study is to determine the distribution and frequency of the different polymorphisms of IL28B rs12979860 in patients with chronic HCV infection studied in our sanitary area.

Methods: A descriptive, retrospective study was conducted to determine the distribution of IL28B rs12979860 in patients with chronic HCV studied in our hospital area for a period of 6 years (January 2011 to January 2017). The IL28 polymorphism determination was performed by real-time polymerase chain reaction (PCR), using specific fluorescent probes for the C and T alleles of SPN rs 12979860. Determination was performed by real-time polymerase chain reaction (PCR), using specific fluorescent probes for the C and T alleles of SPN rs 12979860. The IL28 polymorphism distribution of IL28B rs 12979860 in patients with chronic HCV infection studied in our sanitary area.

Conclusions:

- The typing of the IL28B polymorphism allows evaluating the probability of response to INF plus ribavirin in patients with chronic HCV allowing the adjustment thereof over time by following the individual requirements increasing it in individuals with low rates of sustained viral response to treatment with IFN alpha and ribavirin.

- As in the literature consulted, the CC genotype was found in 36.31% (895/2465) were homozygous CC, 49.86% (1229/2465) were heterozygous CT and 14.83% (341/2465) were homozygous TT.

- The CC genotype was found in 36.31% (895/2465) were homozygous CC, 49.86% (1229/2465) were heterozygous CT and 14.83% (341/2465) were homozygous TT. The aim of this study is to determine the distribution and frequency of the different polymorphisms of IL28B rs12979860 in patients with chronic HCV infection studied in our sanitary area.

Results: From January 2011 to January 2017 2465 patients were analyzed. Males represented 71% of the studied population with an average age of 54 years with a range of 29 to 79. Women accounted for 29% with an average age of 51 years and a range of 31 to 83 years. The analysis of the distribution of IL28B polymorphism results showed that 36.31% (895/2465) were homozygous CC, 49.86% (1229/2465) were heterozygous CT, and 13.83% (341/2465) were homozygous TT.

- The CC genotype was found in 36.31% of these patients. The typing of the IL28B polymorphism allows evaluating the probability of response to INF plus ribavirin in patients with chronic HCV allowing the adjustment thereof over time by following the individual requirements increasing it in individuals with CC genotype and looking for new therapies in the CT and TT genotypes.

Expression of Tim-3 in PBMCs and Placental Tissue in Unexplained Recurrent Spontaneous Abortion

X. Zhuang, Qilu Hospital of Shandong University, Jinan, China

Background: The expression of the T-cell immunoglobulin domain, mucin domain-3 (Tim-3) in unexplained recurrent spontaneous abortion (URSA) was investigated.

Methods: im-3 mRNA expression in peripheral blood mononuclear cells (PBMCs) of URSA and control groups was assayed by fluorescent quantitative real-time polymerase chain reaction. Tim-3 protein expression intensity and localization in placental villi and uterine decidua were determined using immunohistochemical assay.

Results: Tim-3 mRNA expression in PBMCs was significantly higher in URSA than in normal controls (1.32 ± 0.13 vs. 1.20 ± 0.06, P < 0.01). Tim-3 was expressed in placental tissue from both URSA patients and normal pregnant females (controls), however, the expression intensity was higher in the URSA group (P < 0.05).

Conclusion: Increased Tim-3 expression in PBMCs may affect maternal-fetal immune tolerance and facilitate pathogenesis of URSA.

ABL1 transcripts levels in peripheral blood mononuclear cells of healthy individuals: comparison of three automated nucleic acid extraction instruments.

**Background:** The ABL1 mRNA is widely used as the reference gene for quantification of leukemic fusion transcripts, such as BCR-ABL and PML-RARA. The ABL1 quantification is used to ensure the analytical assay sensitivity, which is essential for the minimal residual disease monitoring along and after therapy. A sensitive BCR-ABL and PML-RARA RT-qPCR process should quantify 10^5 copies of ABL1 transcripts in every reaction. Here, we compared three automated systems for nucleic acids (NA) extraction from peripheral blood mononuclear cells (PBMC) to evaluate the ABL1 levels returned by each system.

**Methods:** PBMC of healthy volunteers (60 women and 26 men, average age 42.21±17.59 years) was isolated from EDTA-blood samples (4 mL, n=86). Residual red blood cells were removed using ammonium chloride-based buffer (BD Biosciences). PBMC was resuspended in the initial sample volume required for each equipment. PBMC total nucleic acids (or RNA) were extracted on QIAcube (Qiagen) using RNeasy kit (PBMC resuspended in 600 uL, RNA elution in 100 uL.) (n=24); on MagNA Pure 96 (Roche) using DNA/Viral large volume kit (PBMC resuspended in 1mL, NA elution in 100uL) (n=32); or on easyMAG (Biomerieux) (PBMC resuspended in 1mL, NA elution in 65 uL.) (n=30). ABL1 mRNA was amplified by one-step RT-qPCR using Europe Against Cancer primers/probes and QuantNiova probe master mix (with mRNA) (Qiagen) on Light Cycler 480 II or 480 (Roche). Quantification standard curves were constructed with sDNA oligos corresponding to the ABL1 primerless molecular target. Medians ABL1 copy number per reaction were compared using Kruskal-Wallis test followed by Dunn’s multiple comparisons test. The percentage difference between samples with higher than 10^5 copies per reaction of ABL1 transcripts were compared by Chi-squared test followed by Marsaciculo procedure (Multiple comparisons).

**Results:** The median (Max-Min) of ABL1 copies per reaction was 7.5x10^4 (1.5x10^5-2.4x10^5) for QIAcube, 1.3x10^5 (1.7x10^5-5.8x10^5) for MagNAPure and 1.1x10^5 (2.6x10^5-7.6x10^5) for easyMAG. The median copy number obtained using easyMAG and MagNAPure were similar (p=0.40). However, both were different from QIAcube results (p=0.0001 and p=0.0031, respectively). The percentage of samples that achieved 10^5 copies of ABL1 transcripts per reaction was 25% for QIAcube (p=0.0001 versus easyMAG and p=0.0083 versus MagNA-Pure), 85% for MagNA-Pure (P=0.27 versus easyMAG) and 97% for easyMAG.

**Conclusion:** EasyMAG and MagNA-Pure extracted a higher median copy number of ABL1 transcripts per reaction compared to QIAcube. Additionally, a higher percentage of samples reached the limit of 10^5 copies of ABL1 transcripts using the prior instruments. These results suggest that easyMAG and MagNA-Pure can consistently provide better sensitivity for the assessment of the minimal residual disease of leukemic fusion transcripts. The limitation of this study is its small number of tested samples.

Frequency distribution of p210, p190, and p230 fusions transcripts on a BCR-ABL1 laboratory routine

M. Kolarik, J. Wernack, P. G. Mesquita, R. Jácomo, L. Abdalla, G. Barra. Laboratório Sabini, Brasilia, Brazil

**Background:** Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells present in 90% of CML patients that originate from the reciprocal translocation of ABL1 sequences from chromosome 9 to BCR sequences on chromosome 22. Around 95% of the CML patients were reported with e12a2/e13a2 (p210) BCR-ABL1. A very few patients had the BCR-ABL1 fusion e12a2 (p230) is even rarer. Co-expression of p210 and p190 in patients with classical CML or Ph+ ALL is even rarer. Co-expression of more than one BCR-ABL1 fusion was common in patients with high expression levels of p210, 12 (22.22%) co-expressed p190 at low levels. One positive patient (1.85%) had higher expression levels of p230 and co-expressed p190 at a low level. Among the patients with low expression levels of BCR-ABL1 transcripts (<10%), 32 (59.25%) had p210, 1 (1.85%) p230 and 1 (1.85%) p190. Among the p210 with low levels, 9 (28.12%) were at M1 (1-10%), 11 (34.37%) were at M2 (10-1-1%), 11 (34.37%) were at M3 (0.01-0.1%), and 1 (3.13%) was at M4 (0.001-0.01%).

**Conclusion:** Co-expression of more than one BCR-ABL1 fusion was common in samples with high expression levels of p210 and p230, which is in agreement with literature data and may be explained by the alternative splicing. It is also important to point out that clinical laboratories usually do not test p230 BCR-ABL1 and we found the presence of two p230 positive patients and only one p190 positive patient, suggesting the importance of testing for these transcripts on the BCR-ABL1 fusions detection routine. The main drawback was the low number of samples tested.
of the volunteers had the causal mutation identified) and non-sanger-based methods could validate the NGS results.

**B-273**

**Agreement between UV absorbance, automated microfluidic electrophoresis and qPCR methods for DNA quantification**

**Background:** DNA quantification is a critical step for next-generation sequencing (NGS) aiming to investigate genomic phenomena (e.g., mutations in cancer and diseases). Accurate quantification of the DNA starting material ensures consistent and reproducible results from NGS library preparation. Here, we aim to compare three methods with different methodologies for NGS input DNA quantification.

**Methods:** Genomic DNA from 28 volunteers was extracted from 200 ul of EDTA-whole blood using MagNA pure 96 DNA and Viral NA Small Volume Kit on MagNA pure 96 instrument (Roche Diagnostics) according to the manufacturer’s specifications. One microelut of extracted DNA was quantified by three distinct methods: UV absorbance (NanoDrop, Thermo scientific), automated microfluidic electrophoresis (TapeStation using genomic DNA screen Tape, Agilent Technologies) and qPCR targeting a 65 bp single copy genomic sequence (absolute quantification of RNase P gene, in-house). Mean DNA concentrations obtained by each method were compared using repeated measures one-way ANOVA with Geisser-Greenhouse correction followed by Tukey multiple comparisons test. Pearson correlation coefficient and Bland-Altman analysis of the tested methods were calculated.

**Results:** The DNA yield (mean ± sd) measured by UV absorbance, automated microfluidic electrophoresis and qPCR were 50.71 ± 30.61 ng/ul, 25.24 ± 11.84 ng/ul and 25.37 ± 10.54 ng/ul, respectively. UV absorbance mean was different from automated microfluidic electrophoresis (p=0.0001) and qPCR (p=0.0001). No difference was observed between automated microfluidic electrophoresis and qPCR (p=0.96).

Correlations coefficient (r) were: 0.65 (p=0.0002) for automated microfluidic electrophoresis and UV absorbance, 0.67 (p=0.0008) for UV absorbance and qPCR, and 0.92 (p=0.0000) for automated microfluidic electrophoresis and qPCR. Bias (%): ± sd and 95% limits of agreement were 53.98% ± 49.57 and -43.18% to 151.1% between automated microfluidic electrophoresis and UV absorbance, 52.47% ± 51.06 and -47.6% to 152.6% between UV absorbance and qPCR, and -2.01% ± 17.25 and -35.86% to 31.76% between automated microfluidic electrophoresis and qPCR, respectively.

**Conclusion:** Here we observed a higher agreement between automated microfluidic electrophoresis and qPCR for genomic DNA quantification. Conversely, both methods showed different results from UV absorbance method. Probably, DNA quantification by UV absorbance is being overestimated due to the co-extraction of RNA. Automated microfluidic electrophoresis and qPCR seems to be comparable (and reliable) quantification methods. However, both methods have their particularities. Automated microfluidic electrophoresis would be adequate for high molecular weight DNA and when information about the DNA integrity is needed (e.g., target NGS sequencing). On the other hand, qPCR would be adequate for fragmented DNA and when information about the presence of PCR inhibitors co-purified during the extraction is necessary (e.g., liquid biopsies and FFPE tissue).

**Analytical Validation of a MALDI-ToF Pharmacogenomic Assay**

G. R. Williams, G. J. Tsongalis, L. D. Lewis, R. D. Nerenz. Dartmouth-Hitchcock Medical Center, Lebanon, NH

2018 AACC Abstract

**RELEVENCE:** Genotyping of pharmacodynamically relevant SNPs is routinely performed when optimizing patient care for therapeutic drugs and has also been hypothesized to be important to predict susceptibility to drug-misuse disorders. Recent combinations of pharmacogenomic biochemical tools and mass spectrometric methods have allowed for sensitive, economical, and rapid processing of patient samples for pharmacogenomic patient profiling in the clinic. Mass Spectrometry is an analytical technique exceptional for a high level of sensitivity which enables successful analysis of sample sizes up to 2 orders of magnitude smaller than that of traditional RT-PCR. Here, we compare the Agena MassARRAY MALDI-ToF analyzer using the PGx74 SNP panel for genotyping of patient samples previously characterized by RT-PCR.

**OBJECTIVE:** The goal of this study was to validate the analytic accuracy and reproducibility of the Agena MassARRAY instrument and PGx74 assay via comparison to previously tested DNA samples with known genotypes. The ultimate goal is to develop a prospective tool to guide opioid usage in patients seeking care from Pain Management providers.

**MATERIALS AND METHODS:** We assessed the ability of the Agena MassARRAY 4.0 MALDI-ToF MS instrument to detect SNPs known to be associated with opioid metabolism and response. The Agena PGx74 panel detects wild type and variant SNP sequences as well as copy number variants in 20 genes, including ABCB1, APOE, COMT, CYP1A2, CYP2B6, CYP2C19, CYP2C9, CYP2D6, CYP3A4, CYP3A5, DRD2, F2, F5, GLP1R, MTHFR, OPRM1, PNPLA5, SLC01B1, SULT4A1, and VKORC1. Archived DNA samples which were previously tested for pharmacogenomic-related SNPs using TaqMan assays were used to assess performance of the Agena PGx74 assay. After multiplex PCR of target regions, a single base extension reaction was performed that allows for simultaneous SNP and copy number variant detection. Accuracy of the PGx74 assay was determined as percent concordance with previous genotypes.

**RESULTS:** Ten samples with known CYP2C19 genotypes were analyzed using the MassARRAY PGx74 multiplex panel. Three specimens were analyzed twice. Of the three generated concordant CYP2C19 results that matched the known genotype on all four replicates. The third specimen generated “no call” results on two of the four replicates. The remaining seven specimens were analyzed twice. Six of these generated concordant CYP2C19 results on both runs while the remaining specimen generated “no call” results on both runs.

**CONCLUSIONS:** The Agena MassARRAY demonstrated accuracy and reproducibility in high quality, previously characterized DNA samples. In lower quality samples, the MassARRAY generated “no call” results rather than incorrect results. The combination of highly sensitive mass spectrometric methods and high-throughput pharmacogenomic biochemical tools may allow for the estimation of patient risk for adverse outcomes following use of opioid therapeutics. The ability to rapidly genotype these specimens is of great utility to providers and patients seeking safe and effective pain relief.
Development of a Type I Diabetes Genetic Risk Array

R. Yade1, M. J. Latten1, H. A. Murray1, M. A. Crockard1, J. V. Lamont1, S. P. FitzGerald1, R. A. Orami2, A. T. Hattersley1, M. N. Weedon1, J. M. Lock2, Randox Laboratories Ltd, Crumlin, United Kingdom, Institute of Biomedical and Clinical Science, University of Exeter Medical School, Exeter, United Kingdom

Background: Differentiating between Type 1 diabetes (T1D) and Type 2 diabetes (T2D) is challenging due to the increasing incidence of childhood obesity blurring the traditional T1D versus T2D timelines. More young people are getting T2D and T1D can occur at any stage in life, but treatment and patient care pathways are very different depending on diabetes type. Besides this, there has been an increasing number of cases of T1D occurring at old age. Currently available diagnostic tests have several limitations in accurately diagnosing diabetes subtypes. Up to 15% of young adults are wrongly classified and treated. The aim of this study was to consider genetic predisposition as an aid to improve diabetes classification. Genetic predisposition to diabetes is largely determined by the presence of human leukocyte antigen (HLA) genes. A number of Single Nucleotide Polymorphisms (SNPs) that tag these genes have been shown to identify increased risk. Genome-wide association studies have identified additional non-HLA SNPs, robustly linked with T1D. Combining these, a 10 SNP genetic risk score (GRS) was developed which can aid discrimination between T1D and T2D, particularly when used in conjunction with clinical features and autoimmune markers.

Methods: The assay employs multiplex Polymerase Chain Reaction (PCR) coupled to Biochip Array Technology (BAT, Randox Laboratories Ltd, Crumlin, UK) to genotype 10 SNPs associated with T1D (Oram et al. 2016). Multiplex SNP-specific PCR amplicons are hybridised and spatially separated onto a grid of discrete test regions on a biochip, followed by chemiluminescent detection on the Evidence Investigator analyser. Assay run time is <3 hours from DNA template to generation of SNP genotypes. Assay optimisation and specificity were realised using pre-characterised DNA samples and initially validated by testing DNA samples (n=259) provided by University of Exeter, with results compared against genotypes using an alternative method.

Results: The Type 1 Diabetes GRS array is capable of rapidly detecting all 10 SNPs associated with T1D. Using the biochip array, all 259 samples (2590 genotypes) were in agreement (99.9%) with genotypes predicted by University of Exeter. Samples tested covered all the genotypes linked to 10 SNPs.

Conclusion: The Type 1 Diabetes GRS array provides a rapid and reliable genotyping test for detecting 10 SNPs associated with T1D. Through an associated algorithm, the array can generate a T1D Genetic Risk Score, which in conjunction with conventional methods, can distinguish T1D from other subtypes. This assay has potential to prevent misdiagnosis of diabetes and facilitate improved diabetic patient management.

Altered Hepatic Oxylipins in Mice Fed Liquid Diets Containing Unsaturated Fat

R. N. Showalter1, A. H. Njoroge2, J. D. Warner1, D. A. Oram1, M. A. Crockard1, S. E. Kinsella2, J. M. Lock2, Randox Laboratories Ltd, Crumlin, United Kingdom, Institute of Biomedical and Clinical Science, University of Exeter Medical School, Exeter, United Kingdom

Background: Lipid metabolism is an important regulatory mechanism that can influence the development of various diseases. The identification of pro- and anti-inflammatory and pro-resolving eicosanoids/oxylipins associated with EtOH-induced liver damage may shed new light into the molecular mechanisms underlying ALD development/progression and might be novel biomarkers and potential new therapeutic targets for ALD. Therefore, further mechanistic studies are warranted.

Results: We examined the effects of EtOH and dietary USF, but not SF, on the expression of inflammatory cytokines and oxylipins in liver tissue. Our results showed that EtOH and dietary USF, but not SF, resulted in more severe liver damage, including elevated plasma ALT levels (a marker of liver injury), enhanced hepatic steatosis, oxidative stress, and inflammation. qRT-PCR analysis for macrophage type M1 and M2 cytokine gene expression revealed that M1-associated proinflammatory cytokines (Tnfa and Il-1beta) were elevated in mice fed the USF+EtOH diet but showed no changes in M2-associated (Tgflbeta and Arg-1) cytokine gene expression. We then performed a targeted lipidomic analysis to measure hepatic levels of bioactive lipid metabolites generated from α3 and ω6 PUFAs, predominantly via three major enzymatic pathways, LOX, COX and CYP/sEH. A total of 17 oxylipins out of 79 detected metabolites were found to be significantly different (increased) in the USF+EtOH compared to SF+EtOH group, and 21 lipid metabolites were different (19 increased and 2 decreased) between the USF+EtOH and control USF-diet fed animals. Liver injury induced by USF+EtOH was associated with increased levels of oxylipins generally involved in pro-inflammatory responses, including 13-hydroxyoctadecadienoic acid, 9,10- and 12,13-dihydroxy-octadecenoic acids, 5-, 9-, 11-, 15-hydroxy-eicosatetraenoic acids, and 8,9- and 11,12-dihydroxy-eicosatrienoic acids, in parallel with an increase in pro-resolving mediators, such as lipoxin A4, 18-hydroxy-eicosapentaenoic acid, and 105,17S-dihydroxy-docosahexaenoic acid. Conclusion: The identification of pro- and anti-inflammatory and pro-resolving eicosanoids/oxylipins associated with EtOH-induced liver damage may shed new light into the molecular mechanisms underlying ALD development/progression and might be novel biomarkers and potential new therapeutic targets for ALD. Therefore, further mechanistic studies are warranted.
An evaluation of Clostridium Difficile Polymerase Chain Reaction on the Roche Cobas 4800.

Introduction
We compared our current method of toxigenic Clostridium Difficile (C. diff) testing against the Roche Cobas 4800 system and CE marked Roche C diff test. Our current methodology, valid for in-house use is the TIB MOLBIOL (Berlin, Germany) LightMix C. difficile Test, optimised for the Roche LightCycler 2.0 (Basel, Switzerland). Sample preparation of the stool is performed on the Qiagen EZ1 (Venlo, Netherlands). In contrast, the Cobas 4800 system comprises the extraction and purification x480 unit while amplification, detection and result rendition takes place on the z480. The only human intervention required is to transfer the prepared PCR plate from the x480 to the z480 unit.

Materials and Methods
We tested 83 anonymised stool samples either retrospectively or as split samples on the Cobas 4800, in accordance with the manufacturer’s instructions. The study also included samples spiked with ATCC strains for Ribotype 027, 405 and AI-56. A lower limit of detection challenge was performed using a serially diluted patient sample, ATCC spiked negative stool and ATCC Ribotype 027 spiked negative stool. A challenge for cross-reactivity was performed by spiking samples up to 1:1 McFarland equivalent concentrations of various organisms. Assay precision was evaluated using the across-threshold values of the negative control, internal control values and the positive control values.

Result
The analytical sensitivity and specificity for the Roche Cobas C diff test was 96.4% and 96.1%, respectively. The lower limit of detection was determined to be less than 100 CFU/ml. The higher detection limit of 1.34% and 1.53% for the internal and positive controls respectively. No false positives were detected with negative samples spiked with E. coli, B fragilis and P mirabilis.

Conclusion
The Roche Cobas 4800 C diff test is able to provide equivalent diagnostic performance on a platform that requires minimal human intervention. Compared to the current method which encompasses several touch-points which increases risk for contamination and mistakes to occur, the 4800 system allows the operator to focus on more complex activities while maintaining high service levels and customer expectations.

Unbalanced inherited complex chromosome rearrangement in a child with congenital malformations and developmental delay

S. D. L. Cueva1, F. K. Marques2, D. R. Santana3, E. Cueva Mateo4, A. C. S. Ferreira5, 1Hermes Pardini Institute (Cytogenetic Division), Vespasiano, Brazil, 1Hermes Pardini Institute (Research & Development Division), Vespasiano, Brazil, 4Hermes Pardini Institute (Genetics Division), Vespasiano, Brazil, 4Hermes Pardini Institute (Progenética Laboratory), Vespasiano, Brazil

Background: Complex chromosomal rearrangements are rare structural aberrations that involve three or more chromosomes and greater than two breakpoints. They are defined as balanced if the chromosomes have the normal chromosomal complement, or unbalanced if there is additional or missing material. Some carriers of complex chromosomal rearrangements appear to have apparently balanced rearrangements but present abnormal phenotypes. Abnormal phenotypes are associated with cryptic deletions or duplications, or disruption of genes at the site of recombination, which cannot be detected by karyotype analysis. With the introduction of microarray analysis as the diagnostic test, large numbers of submicroscopic, pathogenic copy number variants (CNVs) have been uncovered.

Objective: To report a case of unbalanced complex chromosomal rearrangement paternally inherited detected in a child with multiple malformations.

Case report: We report 1-year-old boy with psychomotor development, cardiac pathologies, seizures and syndromic facies. He was born to nonconsanguineous and asymptomatic parents, with no history of abortions. Cytogenetic analysis with G-banding was performed on peripheral blood from the child. An apparently balanced complex rearrangement was found: 46,X,Ins(3;7)(p25;q21.11q21.3)Ins(1;3)(q32;p24.2p25). Parental chromosomes analysis were performed. The mother’s karyotype was normal. The father was found to have a similarly balanced complex karyotype: 46,X,Y,(3;7)(p25;q21.11q21.3)Ins(1;3)(q32;p24.2p25). The proband’s array-based comparative genomic hybridization (array-CGH) analysis revealed two pathogenic alterations: a 17.4 Mb duplication in 3p26.3-p24.3 [arrayCGH 3p26.3-p24.3(61,1636-18,039,381)x3] and a 16.6 Mb deletion in 7q21.11q21.3 [arrayCGH 7q21.11q21.3(78,895,856-95,550,252)x1]. Parental array-CGH analysis were normal. The proband’s analysis is the first case in which occurred simultaneously a 3p26.3-p24.3 duplication and a 7q21.11-q21.3 deletion, therefore, we cannot associate its findings to any case already described. However, many features described in the literature for the alterations separately are coincident and correlated with the clinic of the evaluated patient. The complex rearrangements identified by karyotype analysis were interchromosomal insertions involving chromosomes 1, 3 and 7. A balanced, interchromosomal insertion is characterized by one chromosome with an interstitial deletion and another chromosome with an interstitial insertion.

Molecular Pathology/Probes
Marfan syndrome screening using NGS and MLPA in Brazilian patients

J. O. Rodrigues, F. S. V. Malta, R. L. M. Guedes, E. Cueva Mateo, Hermes Pardini Institute (Research & Development Division), Vespasiano, Brazil

Background: Marfan syndrome (MFS; MIM# 154700) is a rare, autosomal-dominant connective tissue disorder that is caused in the majority of cases by mutations in fibrillin 1 (FBN1; MIM# 134797). This gene comprises 66 exons located in the long arm of chromosome 15 at 15q15.2-q21.1. Mutations in the transforming growth factor-β receptor 1 and 2 genes (TGFBR1 and TGFBR2) on chromosome 3 have also been identified in a subset of MFS patients who did not carry FBNI mutations. The disorder is characterized by variable manifestations in the cardiovascular, ocular and skeletal systems. Diagnosis is based on familial history of MFS, FBNI mutation analysis and specific phenotypic characteristics, including ectopia lentis, aortic dilatation or dissection and skeletal features. The incidence is currently estimated to be of 1-3 per 10000 individuals, although this could be under-estimated due to misdiagnosis. Next Generation Sequencing (NGS) and Multiplex Ligation-Dependent Probe Amplification (MLPA) have been introduced into DNA diagnostic laboratories for the detection of molecular genetic alterations that are of diagnostic and prognostic significance, such as SNPs and large gene duplications and deletions. Objective: Investigate the presence of gene mutations in eight Brazilian patients with familial history and clinic diagnostic of MFS. Methodology: Patients were tested using the commercial MLPA kits P230-B1 and P066-B2 (MRC-Holland) for FBNI, TGFBR1 and TGFBR2, following manufacturer’s instructions and the FBNI gene was sequenced on Ion Torrent PGM sequencer. Variant analysis was performed using Ion Reporter software and detected variants were classified according to 2015 ACMG-CAP guideline. Furthermore, linkage analyses were performed with genetic markers near FBNI allele related to the altered phenotype. Results and Discussion: One patient presented a large disruptive heterozygote deletion in FBNI gene from exons 50 to 66. No alterations were detected for MLPA for TGFBR1 and TGFBR2. A total of 14 (13 SNPs and one deletion) variants were detected considering all patients with four novel variants not currently annotated in public databases such as ClinVar and dbSNP. Three patients presented novel likely pathogenic variants in exons 14, 29 and 64. One patient presented a novel pathogenic variant in exon 16. Eight variants were benign or likely benign and the remaining 2 variants were of unknown significance. No alterations were found for three patients; therefore, the genetic factor contributing for the disease is probably located in their intronic or regulatory regions or in genes other than those analyzed. Conclusions: MFS is a genetic disorder with considerable morbidity and mortality, which early diagnosis is essential for the prevention of aorotic events. The description of novel variants related to MFS is an important support for medical counseling and diagnosis.

Analyses on the genotype and phenotype of pediatric deaf patients with cochlear implantation

X. Cheng, Y. Xu, J. Cao The First Affiliated Hospital of Anhui Medical University, Hefei, China

Background: National surveys show that the number of handicapped people with hearing impairment in China has reached to more than 27 million. Cochlear device implantation (CDI) is still the only reliable choice for hearing treatment in severe sensorineural hearing loss. This study sought to screen the frequency of mutations and the main types of the mutations, to provide theoretical basis for further analysis on the differences in hearing and speech rehabilitation after CDI in children with different genetic mutations and to provide clinical guidance for children with deafness who need CDI. Methods: A total of 42 patients that did not pass newborn hearing screening and were diagnosed as congenital infant deaf had peripheral blood samples collected at the First Affiliated Hospital of Anhui Medical University. Genetic testing was performed by fluorescence PCR on three high-frequency deafness susceptibility hot spot gene mutations: GJB2, SLCO2A4 (PDS) and mitochondrial tRNAs 12s rRNA. Results: Four out of 42 patients (9.52%) had GJB2 235delC heterozygote mutation, 8 (19.05%) had SLCO2A4 mutation (1 case of IVS7-2A-G homozygote mutation, 1 case of 1174A>T homozygote mutation, 1 case 2168A>G homozygote mutation with IVST7-2A>G heterozygote mutation, 3 cases of 1174A>T homozygote mutation, and 2 cases of 1174A>T homozygote mutation) and 2 (4.76%) had mtDNA 12s rRNA 1555A>G heterozygote mutation. Conclusion: Among the 42 cases of pediatric patients with congenital deafness and went through cochlear implantation, the detection rate of the three common deafness gene mutations in China was 33.33%, of which the mutation of SLCO2A4 had the highest frequency, GJB2 gene was the next, and the mutation of mitochondrial gene was not common. This study provided a theoretical basis for further analysis of children with different gene mutations in hearing and speech rehabilitation after cochlear implantation, and provides clinical guidance for children with deafness who need cochlear implantation.

limit of detection of the molecular assays mix® modular giardia for the study of giardia lamblia in coprolological samples

E. Lepe Balsalobre1, I. Peral Camacho1, M. Viloria Peñas1, J. Guerrero Montavez2, A. Moro Ortiz1. 1Virgen de Valme University Hospital, Seville, Spain, 2Virgen del Rocío University Hospital, Seville, Spain

Background: The diagnosis of persistent diarrhea due to Giardia lamblia can be complicated by the low parasitic burden. The most used diagnostic technique by laboratories, is microscopy, due to its low cost and simplicity. However, traditional microscopy requires time and experience.In recent years, real-time PCR has become an important alternative for the diagnosis of intestinal parasitosis, especially due to its greater specificity and sensitivity to microscopy, an aspect that has been evaluated in patients with acute diarrhea. The aim is to evaluate the detection limit of the LightMix® Modular Giardia Roche Diagnostics molecular technique for the detection of Giardia lamblia cysts.Methods: We studied 33 samples of stools parasitized with Giardia lamblia and considered microscopically as high parasitic concentration (~840-cysts/μL, 1), medium (~490-cysts/μL, 2) and very low (~30-cysts/μL, 3). Serial dilution was performed in duplicate in each sample, microscopically quantifying each one (number of Giardia lamblia cysts per microcentrifuge) in Barker’s chamber. The limit of detection was defined as the lowest dilution that showed a positive result in 100% of the cases. The extraction phase was carried out in MagnaPure equipment (Roche Diagnostics) and for this the samples were diluted 1/10 in STAR Buffer and subsequently pre-treated with MagNApure Bacteria Lysis-Buffer. Molecular amplification was performed by real-time PCR (Roche Diagnostics) amplifying a 62 bp fragment of the 18s rRNA gene from Giardia on a Cobas® 4800 device. Results: Limit of detection was 3-10 cysts/μL. Therefore, samples parasitized with a low number of cysts of Giardia lamblia could be negative in the molecular study of the stools samples of these patients. In addition, the small volume of sample used in the extraction phase, together with the difficulty of breaking the cysts in the pretreatment, may limit the usefulness of molecular techniques as an alternative to conventional microscopy.

Proficiency testing in NSCLC-related multigene molecular detection by next generation sequencing in China

P. Gao, R. Zhang, J. Li. Beijing hospital, Beijing, China

Background: Non-small cell lung cancer (NSCLC) is heterogeneous group of carcinoma and stands 70% of cases in lung cancer. As targeted therapies based multiple-gene testing have improved the outcomes of NSCLC patients and decreased cost of next-generation sequencing (NGS) technology have been widely used as clinical diagnostic assays in numerous laboratories, the accuracy of oncogenic driver mutation detection becomes an indispensable component in genome-directed cancer therapy. Hence, National Center for Clinical Laboratories (NCCL) organized a proficiency testing (PT) for NGS-based multiple genetic detection in NSCLC in 2017, 2018.
on the purpose of evaluating the multiple gene testing capability in China. **Methods:** Mimicking NSCLC-related clinical samples were provided to 101 participating labora-
tories, each with a mock clinical case report. Laboratories were required to use their
routine NGS methods to perform the genetic testing and submitted all the variants
involved in their detection range within three weeks. Results were evaluated based
on predefined marking criteria, the qualified score was set at higher than 90 points.
**Results:** Overall, ninety-five laboratories reported their results on schedule. Fifty-two
laboratories were considered as qualified while forty-three had completely correct
results. More than three hundred errors were divided into 4 parts: 32 false-negatives,
224 false-positives,48 mutation errors and 54 nomenclature errors. The detection rates
diagram gRNA and fusion gene were more than 85% while laboratories had a poor ability
in detecting indels, the detection rate of ERBB2 c.2326delGinsTTAT (p. Gly776delins-
LeuCys) was only 62%. **Conclusion:** Our PT results indicated that the detection capability of Chinese laboratories must be improved to further increase the accuracy of
NGS-based multigene molecular analysis to ensure reliable results for selection of
precision therapy.

**Quantitative detection of JAK2-V617F mutation using droplet digital PCR for molecular diagnostics of myeloproliferative neoplasms**

P. D. R. Cirillo¹, F. K. Marques¹, T. M. dos Santos², E. Cueva Mateo³,
¹Hermes Pardini Institute (Research & Development Division), Vespasiano, Brazil,
²Hermes Pardini Institute (Genetics Division), Vespasiano, Brazil

**Background:** Myeloproliferative neoplasms (MPNs) are chronic neoplastic disorders
defined as abnormal increases in mature peripheral blood cells, resulting in the aberr-
art clonal proliferation of hematopoietic progenitors. MPNs consist of chronic my-
eloid leukemia (CML), polycythemia vera (PV), essential thrombocytosis (ET), and
myelofibrosis (MF). Karyotyping and BCR-ABL rearrangements tests are indicated
for diagnostic and prognostic of these disorders. Under negative results, investiga-
tions in genetic and epigenetic processes, but it remains largely unknown if they
are correlated with SCA3/MJD pathogenesis. Therefore, the objective of this work
was to investigate the significance and potential role of circRNAs in SCA3/MJD.

**Methods:** Here, we adopted next-generation sequencing (NGS) to examine the ex-
pression profile of circRNAs and mRNAs in cerebrospinal fluid (CSF) samples and
peripheral blood samples from 11 SCA3/MJD patients and 10 healthy controls.

**Results:** Our data showed that circRNAs and mRNAs profiles presented a to-
tal of 262 circRNAs and 1001 mRNAs commonly expressed in both CSF sam-
plies and peripheral blood samples of SCA3/MJD patients. Among them, 14 cir-
cRNAs as well as 429 mRNAs were upregulated and 42 circRNAs as well as
549 mRNAs were downregulated in SCA3/MJD group. The expression level
changes of 5 differentially expressed circRNAs estimated by qRT-PCR were
in accord with NGS data. Moreover, hsa_circ_0019149 (AUC:0.953; 95% CI:
0.911–1.005) were the most upregulated and significantly associated with SCA3/
MJD, which could be identified as novel candidate diagnostic biomarker for the
disease. Significantly enriched signaling pathways were involved in apoptosis,
protein degradation, etc. The viability of cells increased markedly and polyQ-
ataxin3 (polyQ-ataxin3 expression in SY-SH5Y/SCA3 cell models. Next, quantitative real-time reverse transcription polymerase chain reaction (qRT-
PCR) was performed to validate NGS data. ROC analysis was also used to evaluate the
predictive power of candidate circRNAs. In order to elucidate potential func-
tions and signaling pathways involved in the pathogenesis of SCA3/MJD, we ap-
plied Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG)
pathway analysis of the differentially expressed mRNAs and parent genes of
circRNAs. Furthermore, after the knockdown or overexpression of candidate cir-
cRNA, MITT assay along with flow cytometric assays were used to assess changes
in cell viability as well as apoptosis, and Western blot was performed to analyze
the disease protein—polyQ-ataxin3 expression in SY-SH5Y/SCA3 cell models.

**Results:** Our data showed that circRNAs and mRNAs profiles presented a to-
total of 262 circRNAs and 1001 mRNAs commonly expressed in both CSF sam-
plies and peripheral blood samples of SCA3/MJD patients. Among them, 14 cir-
cRNAs as well as 429 mRNAs were upregulated and 42 circRNAs as well as
549 mRNAs were downregulated in SCA3/MJD group. The expression level
changes of 5 differentially expressed circRNAs estimated by qRT-PCR were
in accord with NGS data. Moreover, hsa_circ_0019149 (AUC:0.953; 95% CI:
0.911–1.005) were the most upregulated and significantly associated with SCA3/
MJD, which could be identified as novel candidate diagnostic biomarker for the
disease. Significantly enriched signaling pathways were involved in apoptosis,
protein degradation, etc. The viability of cells increased markedly and polyQ-
ataxin3 expression decreased following the knockdown of hsa_circ_0019149,
while overexpression of hsa_circ_0019149 had the opposite effects on cells.

**Conclusions:** These findings were the first report of differentially expressed circRNAs in SCA3/MJD, indicating a possible role for circRNAs as potential dynamic monitor-
ign markers and possibly original diagnostic or therapeutic targets for the disease.
Also, our results provided novel insights into the mechanisms of the patho-
logical process as well as important cues for further functional studies of the disease.

Ectopia Lentis diagnosed by NGS sequencing of a new pathogenic variant of the FBN1 gene.

A. Espuch Oliver, S. García Linares, J. L. García De Veas Silva, M. T. De Haro Romero, G. De Vicente López, T. De Haro Muñoz, Hospital Universitario Virgen de las Nieves, Granada, Spain; Hospital Universitario San Cecilio, Granada, Spain

**Background:** Marfan syndrome (MS) is a systemic connective tissue disease characterized by a variable combination of cardiovascular, musculoskeletal, ophthalmological and pulmonary manifestations. In most cases it is due to mutations in the FBN1 gene (15q21), which codes for an essential connective tissue protein, fibrillin-1. There are identified borderline forms of the disease secondary to mutations in the TGFBR2 gene (3p22), which codes for TGF-beta’s receptor. On the other hand, isolated Ectopia Lentis (IEL) is a rare eye disorder characterized by subluxation of the lens and a significant visual acuity decrease. Its prevalence is unknown, having been described around 90 cases to date, mainly in Europeans. Other manifestations include: congenital anomalies of the iris, spherophakia, abnormal iridoconal angle, iridodonesis, coloboma of the lens, refraction errors, cataracts of early onset, amblyopia, displacement of the pupils (ectopia lentis et pupillae). The disease is due to recessive mutations in the ADAMTS4 gene (1q21.2) and dominant mutations in the FBN1 gene (15q21.1). By definition, patients with IEL have no associated systemic abnormalities, although cardiac and skeletal examinations should be performed to help exclude Marfan syndrome.

**Objective:** This report describes a case of a patient with crystal subluxation and other ocular anomalies and suspicion of Marfan syndrome, which is finally diagnosed of IEL by NGS sequencing.

**Case report:** 5 years female patient, without family history of interest. Size: 116.1cm (p76, 0.71 SD), weight: 16.9kg (p18, -0.92 SD), BMI: 12.54% (p7, -1.54 SD), body surface: 0.74m², Tanner 1. Presents, in the right eye: superolateral subluxation of the lens with coloboma of the same, phacoedema (lens remor), amautosis (total blindness), endotropia (deviation of the eye) intermittent to + 10°, left eye: superolateral subluxation of the lens, phacoedema, decreased visual acuity (0.5 PIGAS-SOU). The electrocardiogram and Doppler-echocardiogram showed no pathology.

**Methods:** NGS sequencing of the coding regions of the FBN1, TGFBR1 and TGFBR2 genes was performed: DNA amplified by multiplex PCR with the Ion AmpliSeq kit, Ion Torrent platform sequencing, bioinformatic analysis using Thermo Fisher Scientific Variant Reporter, with an average coverage obtained from 616.987X, covering 96.03% of the coding regions at 20X by massive sequencing and the rest by capillary sequencing.

**Results:** A variant of uncertain clinical significance c.6801C> A (p.Asn2267Lys) is detected in heterozygosis in exon 56 of the FBN1 gene (sense change mutation). In order to determine if this change is inherited or de novo, genetic study was done to the parents and the brother, who didn’t present the variant.

**Conclusions:** This alteration has not been previously described in the literature, so it’s considered of unknown clinical significance. However, several bioinformatic tools specialized in the prediction of the effect of mutations (Polyphen, SIFT, MutationTaster) classify it as deleterious. Compatible in silico prediction, the fact the variant found in our patient is de novo and the pathophysiology context of the FBN1 gene alterations and the proteins it encodes, we assume that the mutation c.6801C> A (p.Asn2267Lys) of the FBN1 gene is responsible for the diagnosis of isolated ectopia lentis.

**B-290**

The serum has a higher yield of Janus kinase 2 V617F somatic mutation compared to the paired EDTA-whole blood sample.

**Background:** Janus kinase 2 (JAK2) V617F is a somatic mutation of blood cells, usually detected in genomic DNA extracted from nucleated cells of the whole blood. As coagulation releases genomic DNA of these cells to serum, this specimen could be used as a source of DNA for the JAK2 V617F detection and quantification. This study aimed to test if JAK2 V617F can be detected reliably in serum and investigate if the percentage of the JAK2 mutant allele in serum is comparable to the rate found in whole blood.

**Methods:** This study enrolled 88 subjects, 28 with positive for JAK2 V617F and 60 healthy volunteers. Paired EDTA-whole blood and serum samples were collected from each participant in two 4 ml tubes: EDTA-whole blood and Vacuette Z serum sep with clot activator (both from Greiner Bio-One). Genomic DNA was extracted from 500 ul of serum or 200 ul of EDTA-whole blood using Magna Pure 96 instrument (Roche) or EasyMag (Biomérieux) according to the manufacturer’s recommendations. EDTA-whole blood and serum extracted genomic DNA were quantified by a qPCR. The JAK2 wild-type (WT) and mutant (MUT) alleles were assessed by separate AS-qPCR reactions using the StepOne real-time system. The RNase P was co-amplified in both reactions to function as a normalizer gene. The percentage of JAK2 MUT allele was calculated by the delta-delta Cq method using JAK2 WT allele as comparator sample. The agreement between the rate of JAK2 mutations in EDTA-whole blood and serum was calculated using Pearson correlation and Bland-Altman analysis.

**Results:** Qualitatively, there was a complete concordance between serum and EDTA-whole blood results (28 positives and 60 negatives). Quantitatively, there was a correlation between serum and EDTA-whole blood results (r=0.987, p<0.0001). The JAK2 MUT yield bias between both specimens was -3.78% and the 95%CI agreement was -15.37% and 7.77%. The mean percentage of JAK2 MUT in serum was 33.89% (31.09) in serum and 30.11% (27.57) in the EDTA-whole blood (p=0.0021).

**Conclusion:** JAK2 V617F mutation could be reliably detected in serum by qPCR using delta-delta Cq method. The JAK2 MUT allele burden in serum was significantly higher than in EDTA-whole blood. Serum results tended to be 3.78% higher than the EDTA-whole results. This finding can be explored to increase the mutant allele detection rate in the routine.
Simplified workflow for PML-RARA quantification in whole blood by automated nucleic acids extraction, multiplex one-step RT-qPCR and ΔACq method

P. G. Mesquita, T. Santa Rita, R. Jácomo, L. Abdalla, G. Barra. Laboratorio Sabin, Brasília, Brazil

Background: Molecular testing for the PML-RARA fusion gene by RT-qPCR is a substantial approach for monitoring the response to therapy and predict relapse of patients with acute promyelocytic leukemia. The most frequent fusions subtypes are bcr1, bcr2 and bcr3 (found in ~55, ~5 and ~45% of the patients, respectively). The quantification assays for these transcripts have been standardized at international level. However, they are laborious and often require multiple steps that are not user-friendly. Thus, the objective of this study was to validate a simplified multiplex bcr1, bcr2 or bcr3 fusion quantitation in whole blood and bone marrow by RT-qPCR.

Methods: We used patient’s specimens, or known amounts of synthetic fusion RNAs spiked into the negative samples. Red blood cells were removed from Buffy coats prior to extraction using Ph其所lyse (BD Biosciences). Nucleic acids were extracted on Magna Pure 96 (Roche). The reaction was designed to quantify bcr1/bcr2 or bcr3 and ABL1 RNA in a multiplexed one-step RT-qPCR reaction performed with Quant-it Nova RT-qPCR master mix (Qiagen) on LightCyclers 480II or 480 (Roche). Europe Against Cancer primers/probes for bcr1, bcr3, and ABL1 and Chen et al. 2015 for bcr2 were used. Ipgosien’s (Quegen) standard curves were used for the absolute quantification of bcr1, bcr2 and ABL1. The sensitivity of the AQC method was evaluated analyzing the amplification efficiencies retrieved from a serial dilution of the synthetic RNAs corresponding to the studied molecular targets. The limit of detection (LoD) was determined by using probit regression analysis to a serial dilution of known amounts of each target. Precision was evaluated by CLSI EP12-A2 method on samples spiked with the high, medium and low amount of target RNA in triplicate for seven days. The accuracy was assessed with spike-recovery method by using Pearson correlation coefficient (r) Blattnik Method. Results: The median (Max-Min) of ABL1 achieved by the proposed workflow was 9.6x10^3 (3.98x10^3-7.11x10^1) copies/sample. bcr1/bcr2 or bcr3 and ABL1 RT-qPCR efficiencies did not differ significantly in all tested occasions (95.18% for bcr1/bcr2; 97.95% for bcr3; 98.6% for ABL1) meaning that the ΔACq method is applicable. The LoD were 0.026% (95%CI 0.015-0.078) and 0.014% (95% CI 0.010-0.031) of PML-RARA/ABL1 for bcr1/bcr2 and bcr3, respectively. Imprecision values for low, medium and high levels of fusion synthetic RNAs, (expressed as CV(%)), were 4.98%, 10.65% and 11.77% for bcr1 and 5.03%, 9.56% and 27.46% for bcr3. In The Spike-recovery experiment, expected and observed measurements revealed a correlation coefficient (r) of 1.0 for bcr1/bcr2 and bcr3, and bias of 0.011 Log for bcr1/bcr2 and 0.035 Log for bcr3. Cross-reactivity between bcr1/bcr2 and bcr3 assays was not observed. Conclusion: We described a reliable and user-friendly workflow for PML-RARA bcr1/bcr2 and bcr3 fusion quantification in whole blood and bone marrow that reduces the number of steps proposed by the current guidelines. The proposed workflow showed acceptable sensitivity, precision, and accuracy. The assay reached the sensitivity at least 4.4-Log reduction based on the bcr1 and bcr3 positive samples. The main drawback in this study is the lack of bcr2 patients’ samples.

M. Al-Turkmani, K. N. Godwin, J. D. Peterson, G. J. Tsongalis. Dartmouth-Hitchcock Medical Center and Geisel School of Medicine at Dartmouth, Lebanon, NH

Background: Molecular tests have been increasingly used in the management of various cancers as more targeted therapies are becoming available as treatment options. The Idylla™ system (Biocrates, Meichelen, Belgium) is a fully integrated, cartridge-based platform that provides automated sample processing (deparaffinization, tissue digestion and DNA extraction) and real-time PCR-based mutation detection with all reagents included in a single-use cartridge. Objective: This retrospective study aimed at evaluating the Idylla™ KRAS and NRAS-BRAF-EGFR492 Mutation Assay cartridges against next-generation sequencing (NGS) using colorectal cancer (CRC) tissue samples. Methods: Forty-four archived formalin-fixed paraffin-embedded (FFPE) CRC tissue samples previously analyzed by targeted NGS were tested on the Idylla™ system. Among these samples, 17 had a mutation in KRAS, 5 in NRAS, and 12 in BRAF as determined using the Ion AmpliSeq 50-gene Cancer Hotspot Panel v2 (Thermo Fisher Scientific). The remaining 10 samples were wild-type for KRAS, NRAS and BRAF. Tow 10 μm FFPE tissue sections were used for each Idylla™ run, one for the KRAS cartridge and one for the NRAS-BRAF-EGFR492 cartridge. All cases met the Idylla™ minimum tumor content requirement for KRAS, NRAS, and BRAF (≥10%). Assay reproducibility was evaluated by testing commercial standards derived from human cell lines, which had an allelic frequency of 50% and were run in triplicate.

Results: The Idylla™ system successfully detected all mutations previously identified by NGS in KRAS (G12C, G12D, G12Q, G13D, Q61E, Q61K, Q61R), NRAS (G12V, G13R, Q61H), and BRAF (V600E). Compared to NGS, Idylla™ had a sensitivity of 100% (CI 90 – 100%). No mutations in the wild-type samples were detected by Idylla™, except for one sample that showed an NRAS mutation upon initial testing. Idylla™ testing was repeated twice on additional sections from this sample and it was negative. The negative result was further confirmed by another NGS test. Analysis of the horizon mutated control samples demonstrated agreement with the expected result for all samples and 100% reproducibility. The Idylla™ system produced results quickly with a turnaround time of approximately 2 hours. For certain mutations, Idylla™ did not distinguish between mutations occurring in the same codon (e.g. p.Q61R/L in KRAS, G12A/V in NRAS, and V600E/D in BRAF). Conclusion: The fully automated Idylla™ system offers reliable and sensitive testing of clinically actionable mutations in KRAS, NRAS and BRAF directly from FFPE tissue sections. Its simplicity and ease of use compared to other available molecular techniques make it suitable for small centers that lack highly trained staff and molecular expertise. Additionally, it can complement NGS and other molecular testing systems at larger diagnostic centers by providing significantly faster turnaround times.

Absolute Quantification of Graft-Derived Cell-Free DNA as a Marker of Rejection and Graft Injury in Kidney Transplantation - Results from a Prospective Observational Trial

M. Oellerich1, M. Shipkova2, V. Schauerte3, T. Asendorf4, P. D. Walson5, N. Mettenmeyer6, M. Kabakchiev7, D. Ellenberger8, T. Friede9, E. Wieland10, V. Schweigner11, E. Schütz12, J. Beck13, 1. University Medical Center Goettingen, Goettingen, Germany; 2. Klinikum Stuttgart, Stuttgart, Germany; 3. University Medical Center Goettingen, Chronic Biomedical GmbH, Goettingen, Germany; 4. Chronic Biomedical GmbH, Goettingen, Germany

Background: Graft-derived cell-free DNA (GcfDNA), a promising new, noninvasive biomarker of allograft rejection and injury status, was investigated in renal transplant (RTx) patients. Methods: In a prospective observational trial, GcfDNA was evaluated at pre-specified visits in 88 RTx patients, followed over at least one year post transplantation. Relative percentage (GcfDNA%) and absolute quantification of GcfDNA copies (GcfDNAcp/mL) were performed as previously described [Beck J et al, Clin Chem 2014; 60 (Suppl.): S194-S195]. Biopsies were obtained upon clinical suspicion of acute rejection. GcfDNA results were compared between patients with and without positive biopsies. Data were analyzed using R 3.4.3 (packages: base, nparmcomp). Pearson correlations were performed on log transformed data. Results: In patients (N=30) without subsequent rejection, active infections, or interventions, GcfDNA was highly elevated (median: 367 cp/mL; 4.20%), presumably due to ischemia/re-perfusion damage, in day 1 post RTx samples (n=10). In all 30 patients GcfDNA values decreased over the first 30 days to a baseline median of 19 cp/mL (0.20%), where it remained throughout the one year observation period. In patients (N=14) with samples (n=21) drawn during biopsy-proven acute rejection (BPAR) periods, median GcfDNAcp/mL was 5-fold and median GcfDNA% of GcfDNA% (2.6-fold higher (86 cp/mL; 0.68% respectively) than the medians observed in samples (n=267) from 62 clinically stable patients without rejection (17 cp/mL; 0.26%). These comparisons were confirmed by GcfDNA medians in 5 patients with negative biopsies (14 cp/mL; 0.18%). Both GcfDNAcp/mL and GcfDNA% were significantly different between patients with BPAR and apparently stable patients (p<0.0001). To compare the diagnostic accuracy of GcfDNAcp/mL and GcfDNA%, the area under the ROC curves (AUC) were calculated in 76 patients. GcfDNAcp/mL (0.88, 95% CI: 0.82-0.92) better discriminated between patients with BPAR and clinically stable patients than did GcfDNA% (0.81, 95% CI: 0.73-0.87). Plasma creatinine was not an independent marker, as it was used clinically as an indication for biopsies. Youden-index (YI)-based diagnostic sensitivity was 90% for GcfDNAcp/mL, and 86% for GcfDNA% obtained from ROC curves. Diagnostic specificity was 76% for GcfDNAcp/mL, and 74% for GcfDNA%. The threshold at maximum YI was 37 for GcfDNAcp/mL, and 0.43 for GcfDNA%. The correlation between GcfDNAcp/mL and GcfDNA% was r=0.75. Creatinine showed a moderate correlation with GcfDNA (cp/mL: r=0.44; %: r=0.41). In a selected patient subgroup (N=25) without clinically suspected rejection and a change of tacrolimus concentrations >60%, in samples (n=78) collected at ≥3 consecutive visits there was a negative correlation (r=−0.49) between tacrolimus and GcfDNAcp/mL. This sug-
gests that GcfDNA may detect silent graft damage due to under-immunosuppression which might increase the risk of de novo DSA formation and subsequent graft loss.

**Conclusion:** This is the first systematic comparison of GcDNAcp/mL with GcDNA%. Absolute GcDNA quantification allowed for a better discrimination than GcDNA% of RTx patients with acute rejection and graft injury, due to less influence of recipient cfDNA variations, and may facilitate personalized immunosuppression.

Validation of pre-analytical procedures of liquid biopsy samples for investigation of the EGFR-T790M mutation by ddPCR in NSCLC Brazilian patients

P. D. R. Cirillo¹, F. L. O. Marinho², C. P. F. N. Machado³, M. C. M. Freire³, E. Cueva Mateo⁴, M. G. Zalis³. ‘Hermes Pardini Institute (Research & Development Division), Vespasiano, Brazil, ‘Hermes Pardini Institute (Genetics Division), Vespasiano, Brazil, ‘Hermes Pardini Institute (Progenética Laboratory), Vespasiano, Brazil

**Background:** Non-small cell lung cancer (NSCLC) represents approximately 85% of all lung cancer types with 5% of survival rate. The T790M mutation in EGFR gene accounts for nearly 50% of the acquired resistance to tyrosine-kinase inhibitors (TKIs). Circulating-free tumor DNA (cfDNA) harboring T790M can be detected even at low concentration in plasma. Pre-analytical best practices is mandatory to ensure optimum yield and quality of the cfDNA. **Objective:** The aim of this study it was to validate the pre-analytical steps and establish the analysis protocol of droplet digital PCR (ddPCR) for measuring the levels of T790M mutation in NSCLC liquid biopsy samples. **Methods:** Plasma obtained from 5 health volunteers and 13 commercial controls (Horizon) with different T790M concentrations it were used to determine the limit of detection (LOD) and limit of quantification (LOQ), respectively. Patient samples were collected from different regions of Brazil to demonstrate the clinical performance of the test. **Training Set:** it were collected blood samples in EDTA (4mL) and PAXgene Blood cfDNA (PreAnalytix) tubes (16 mL) from 5 NSCLC patients. **Validation Set:** blood samples from 38 NSCLC additional patients were collected in EDTA tubes (4mL). EDTA samples were centrifuged, plasma was aliquoted and sent frozen to our center. One aliquot (2mL) of each EDTA sample were processed for qPCR cobas® EGFR Mutation Test v2 (Roche). PAXgene tubes blood samples it were send in room temperature and processed 24hs, 72hs or 168hs after collection. cfDNA samples (EDTA and PAXgene) were collected using QIAamp MinElute Virus and QIAamp Circulating Nucleic Acid kits (both QIAGEN) and yield measured using Qubit 1.0 (ThermoFisher). All cfDNA samples were submitted to ddPCR using T790M ddPCR Mutation Assay (BioRad) and QX100 Droplet Digital PCR System (BioRad). **Results:** The false-positive rate it was 0.12% and LOD stablished was ≥5 positive droplets to call a T790M positive result (95% CI). The expected results for control samples were 0.05, 0.5 and 5% of mutant allele frequency and the observed results were 0.053, 0.63 and 5.4% (r²=0.99) with mean LOQ of 0.57%. Among training set, cfDNA concentration did not show significant statistically difference regardless time-point processing (p=0.6489) and collection tubes (p=0.07). cfDNA yield it was 10 times higher after virus kit collection (mean 0.52 ng/μL) compared to circulating kit (mean 0.05 ng/μL). All these patients were negative for T790M by both PCR methodology, however 4/38 (10%) patients from validation set were positive by qPCR (SQI ≤5) and negative for ddPCR. **Conclusions:** cfDNA collection using virus kit was superior compared to circulating kit. Four patients from validation set (10%) showed discordant results. This could be explained due to the loss of stability of cfDNA from frozen plasma. In addition, recent data has shown inverse correlation between qPCR results with SQI ≤5 and ddPCR T790M negative results. Our data showed that ddPCR is a powerful methodology for detection of low levels of T790M in NSCLC patients, however pre-analytical best practices is crucial for cfDNA stability and ddPCR sensitivity in liquid biopsy samples. COBAS qPCR results with SQI ≤5 should be revised.
